Data Vulnerabilities

Outline

Concepts

What causes vulnerability ?

The famous SQL Injection attack

Trojan

Elimination of vulnerabilities

Hardening MySQL environment

Concepts

Risk

- A **risk** is the potential of gaining or losing something of value

Threat

- A **threat** is a communicated intent to inflict harm or loss on another person

Vulnerability

- A **vulnerability** refers to the inability of a system or a unit to withstand the effects of a hostile environment

Attack vector

- An **attack vector** is a path or means by which a hacker can gain access to a computer or network server in order to deliver a payload or malicious outcome
- An **attack vector** enable hackers to exploit system vulnerabilities, including the human element

What causes vulnerability ?

Software defects

- **Software defects** are accidentally or intentionally built into the code during the software development process and include **design flaws** and **coding mistakes** (35% of successful attacks exploit these types of errors)
- **Design flaws** involve a design decision, that creates an inherently insecure system
- **Coding errors** include both **ordinary software bugs** as well as **features that were put in not by design** but through oversight and as a result of developers not thinking of all the potential consequences
- **Coding errors** include **buffer overflows, race conditions, back doors into the system**, and even **nonrandom random-number generators**

5/22

What causes vulnerability ?

Configuration errors

- **Configuration errors** account for 65% of vulnerabilities
- **Configuration errors** include set up of **unnecessary and dangerous services** when a system is configured, such that it brings up services and allows for connections that are not required
- It is usually caused by installation of a system with a default configuration, rather than with a precisely defined configuration, that eliminates all features, that are not required (it is easier to use default configuration because vendors prefer to offer an **all-enabling starting configuration**)

6/22

What causes vulnerability ?

Access administration errors

- When access control includes [configuration errors](#), entire security model fall apart
- Because most complex systems have elaborate [access control schemas](#) based on the concepts of [groups](#), [roles](#), [permissions](#), [delegation](#), etc it is easy to get the errors in access control configuration
- It is very hard to detect the cases, that exploit such errors, because it cannot be detected by the intrusion detection or other monitoring systems due to the incorrect assumptions, that outside access looks correct

The famous SQL Injection attack

SQL injection is a technique, that exploits the applications using relational databases as their back end

The technique uses the fact, that applications have an available connection to a database and that the application composes SQL statements and sends them to a database server to extract data or to perform certain functions

SQL injection uses a fact, that many of these applications compose such SQL statements by doing string concatenation of the fixed part of SQL statements along with the user supplied data, that forms **WHERE** clause or additional subqueries

The technique is based on intentionally malformed user-supplied data, that transform SQL statements from an innocent form into a malicious call, that causes unauthorized access, deletion of data, or even theft of information

In all cases **SQL injection** as a technique, that is based on using bugs and vulnerabilities in an application

9/22

The famous SQL Injection attack

For example, assume that we would like to implement an interface, that can be used to login a user to a system

The diagram shows a user interface with a green vertical bar on the left. It contains two input fields: 'USER ID:' and 'PASSWORD:'. Below these fields are two buttons: 'Logon' and 'Enroll'. The buttons are enclosed in a box with a border of dashes and plus signs. A label 'User interface' is positioned in the top right corner of the interface area.

The application receives `USER ID` and `PASSWORD` and it authenticates by checking `USER ID` and `PASSWORD` in `USER` table

Additionally, the application does not validate what a user typed into these two fields and SQL statement is created by string concatenation

10/22

The famous SQL Injection attack

The following piece of code implements the authentication

```

sqlString = "SELECT USERID FROM USER WHERE USERID = ' " &userID& " ' AND PWD = ' "
            &pwd& " ' ";
result = GetQuery Result(sqlString);
if (result = "") then
    userHasBeenAuthenticated = False
else
    userHasBeenAutheticated = True
end if;

```

Embedded SQL

What happens when a user intentionally types in a malicious code like

```

USER ID: ' OR ' ' = '
PASSWORD: ' OR ' = '

```

Data entry

In such a case `sqlString` variable obtains the following value

```

SELECT USERID FROM USER WHERE USERID = '' OR '' = '' AND PWD = '' OR '' = ''

```

SELECT statement

11/22

The famous SQL Injection attack

In such a case `sqlString` variable obtains the following value

```
SELECT statement  
SELECT USERID FROM USER WHERE USERID = '' OR ''= '' AND PWD = '' OR ''=''
```

Interpretation of `WHERE` condition returns `TRUE` because empty string is equal to empty string (`' ' = ' '`) and evaluation of disjunctions

`USERID = ' ' OR ' '= ' '`, and `PWD = ' ' OR ' '= ' '`

returns `TRUE` and finally evaluation of conjunction `USERID = ' ' OR ' '= ' ' and PWD = ' ' OR ' '= ' '` returns `TRUE`

Hence `result` is not empty and a variable `userHasBeenAutheticated` is set to `True`

Hardening MySQL environment

Trojan

A **Trojan** is an unauthorized program contained within a legitimate program

A legitimate program is modified by placement of unauthorized code with it

A legitimate program seems to do one thing but it actually does several other operations without your knowledge or agreement

The word "**Trojan**" comes from the myth about the **City of Troy** in which the Greeks gave their enemy a "gift" – huge wooden horse as a gift during a war

The Greek soldiers were hidden inside the horse

The soldiers stormed out of the horse during the night and they conquered the **City of Troy**

Trojans (or **Trojan horses**) are one of the main forms of attack that have gained "fame" on the desktop computers together with **worms**, **viruses**, and other **malicious software**

14/22

Trojan

A **Database Trojan** is an attack that consists of two phases: the injection of the malicious code and the calling of the malicious code

It is difficult to track a **Database Trojan** because of separation in two phases, it is difficult to associate two apparently not related events

A **Database Trojan** after it is inserted into the system may stay in the system for a long time (“sleeper”) until it is activated

15/22

Trojan

There are four categories of **Trojan** attacks:

- An attack that both injects a **Trojan** and calls it
- An attack that uses an oblivious user or process to inject a **Trojan** and then calls it to extract the information or perform an action within a database
- An attack that injects a **Trojan** and then uses an oblivious user or process to call a **Trojan**
- An attack that uses an oblivious user or process to inject a **Trojan** and also uses an oblivious user or process to call a **Trojan**

An example of using an oblivious user is a scenario when a junior developer gets some procedural code, for example, trigger or stored procedure from someone he/she does not know and then uses this code without fully understanding what it is doing.

Trojan

Elimination of vulnerabilities

Hardening MySQL environment

Elimination of vulnerabilities

Track processing of stored procedures

- Create baseline for a set of stored procedure
- Monitor all divergences from a baseline
- Log information and analyse the logs
- Implement a real-time alert
- Implement base-line capable firewall

Control creation of and changes to procedures and triggers

Watch for changes to run-as privileges

Closely monitor developer activity on production environments

Monitor creation of traces and event monitors

Be aware of SQL attachments in e-mails

Hardening MySQL environment

Hardening MySQL environment

Physically secure server on which MySQL lives

Use the following values of system variables

- `local_infile = 'OFF'` to disable `LOCAL` in `LOADDATA` statements
- `skip_show_database= 'OFF'` to ensure that `show databases` command only lists databases for which the user has some kind of privilege; in a more restrictive approach use `skip-show-databases` option
- `secure_auth= 'ON'` to disallow authentication for accounts that have password from earlier versions
- `skip-name-resolve='ON'` Do not resolve host names when checking client connections and use only IP addresses

Do not grant `PROCESS`, `FILE`, or `SUPER` privileges to non-administrative users

Do not run MySQL server on the same host as Web server in order to force remote connections

Ensure strong password for a user `root`

[In HTML view press 'p' to see the lecture notes](#)

20/22

Hardening MySQL environment

Disallow the default full control of the database to local users and disallow the default permissions for remote users to connect to a database

Do not use MySQL prior to version 4.1

Limit privileges to the `load_file` function

Disallow developers to access production database servers

Enable auditing
