Generalization

(Simplified) Class of Objects

A database suppose to contain information about **people**

PERSON

A rectangular box with a header and a name of class (**PERSON**) inside a header represents a **(simplified) class of objects**

A **person** is described by a **social security number**, **name**, **date of birth** and **address**

PERSON
ssno
name
dob
address

The names of attributes are listed within a rectangular box one name of attribute per row

(Simplified) Class of Objects

A **person** has from one to five **email addresses** and zero or more **phone numbers**

PERSON
ssno
name
dob
address
email[1..5]
phone[*]

Multiplicity of attribute like [1..5] (from one to five), zero or more ([*] or [0..*]), one or more ([1..*]), optional (zero or one, [0..1]), from "m" to "n" ([m..n]) follows a name of attribute

Default **multiplicity** is "one" ([1])

(Simplified) Class of Objects

A **person** is described by an optional country of origin and age (/ in front of attribute name **age** denotes a **derived attribute**)

PERSON
ssno
name
dob
address
email[1..5]
phone[*]
contry[0..1]
/age

(Simplified) Class of Objects

A **person** is identified by a **social security number** and independently by a triple (name, date of birth, address)

PERSON	
ssno	ID1
name	ID2
dob	ID2
address	ID2
email[1..5]	
phone[*]	
contry[0..1]	
/age	

A tag **ID_x** following a name of attribute denotes an **identifier**

If the same tag (e.g. **ID₂**) follows the names of several attributes then it means that an **identifier** consists of several attributes

If an **identifier** consists of several attributes then it means, that each object in a class is identified by a **tuple of values** of the attributes

An **identifier** which consists of several attributes is called as a **composite identifier**

(Simplified) Class of Objects

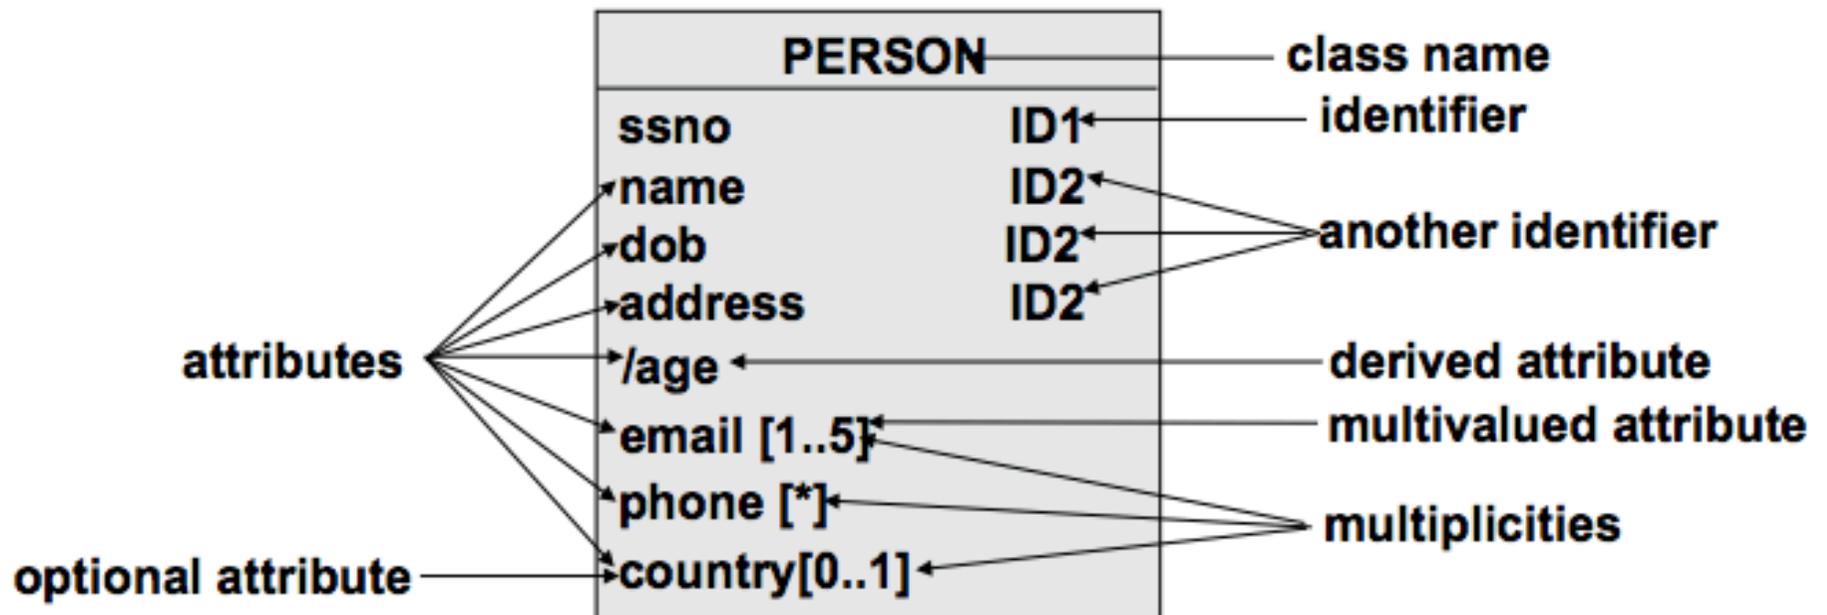

A **vehicle** is described by a registration number, manufacturer, model, year when manufactured and optional fuel consumption

Each **vehicle** has a different registration number

VEHICLE	
rego#	ID1
manufacturer	
model	
year	
fuel[0..1]	

(Simplified) Class of Objects

Summary

Graphical Notations for Conceptual Modeling

(Simplified) Class of Objects

Association

Link Attribute

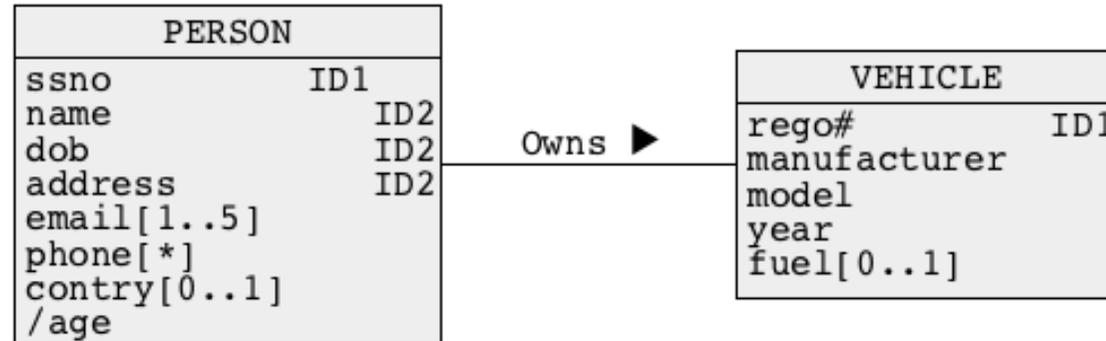

Association Class

Qualification

Generalization

Association

A person owns a vehicle

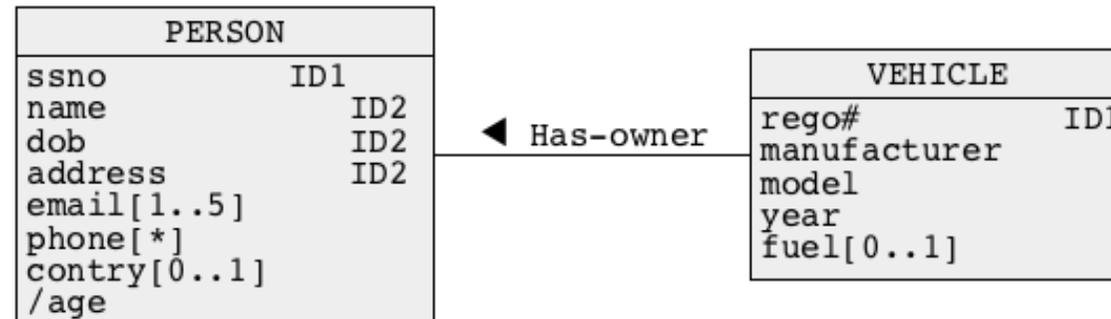

A solid line that connects two classes represents an **association**

A name above a line is an **association name**

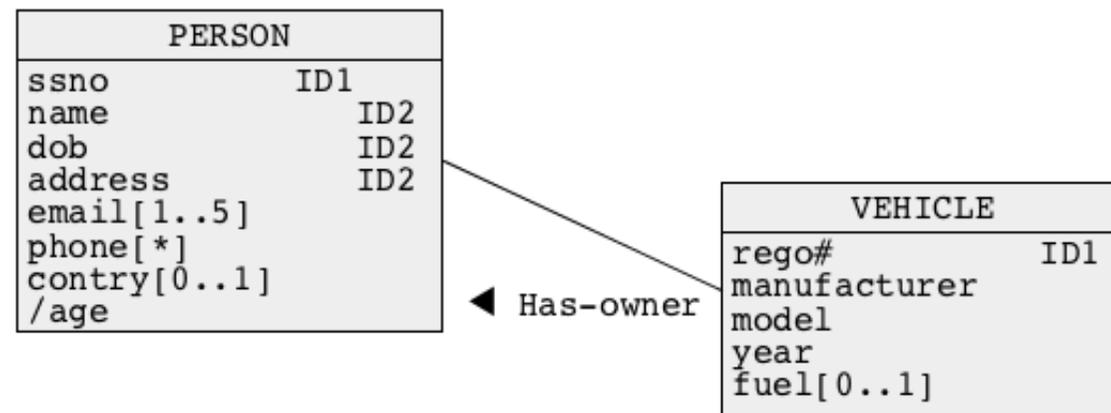

An **association name** if followed (preceded or located above or below) by a small solid triangle, that represents a **direction of interpretation** of an association

Association

A vehicle **has** an owner

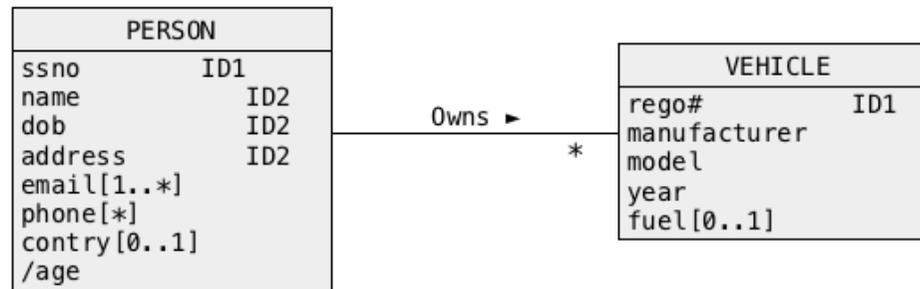

Locations of classes and associations in a diagram are immaterial

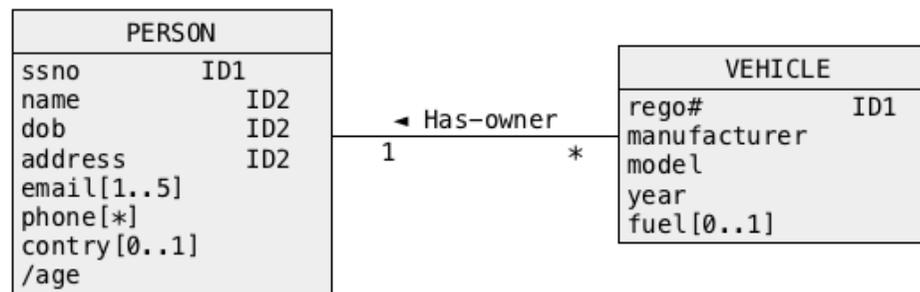

Association

A person owns zero or more vehicles

A vehicle has one owner

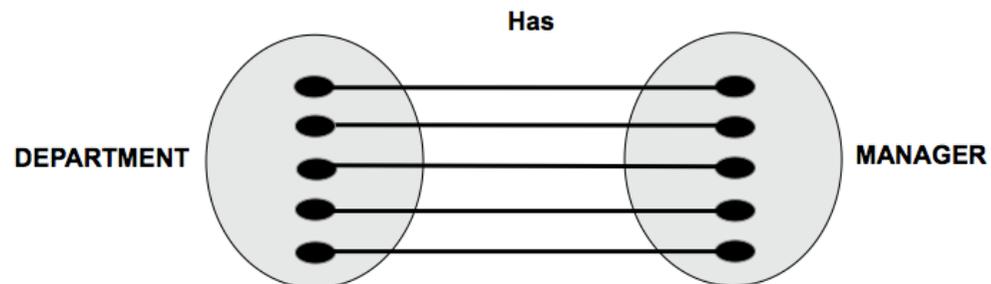

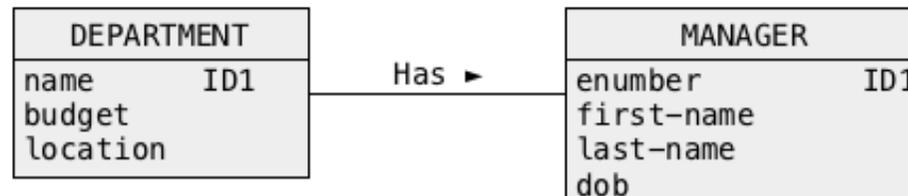

Multiplicities of association are located at both ends of a line that represents an association

Association

One-to-one association

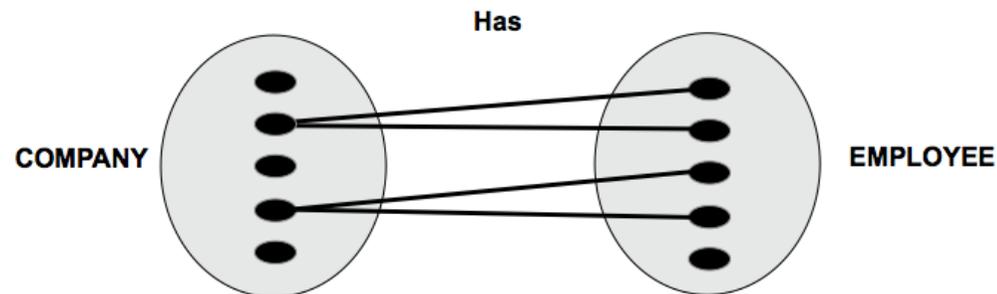

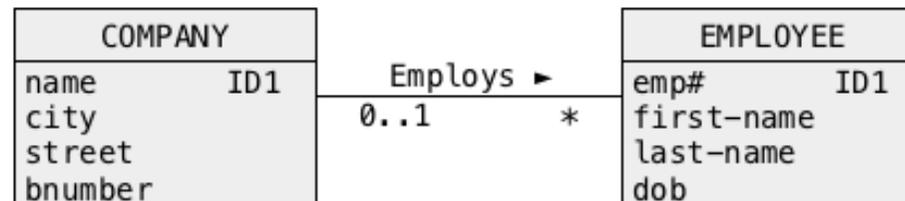

- A department **has** a manager
- A department has exactly **one** manager
- A person who is a manager manages exactly **one** department

Association

One-to-many association

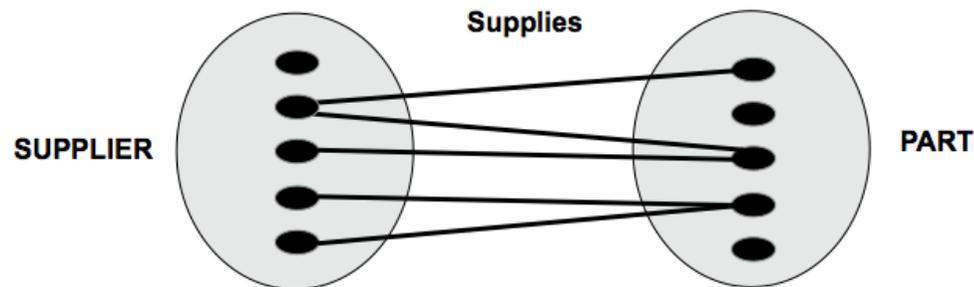

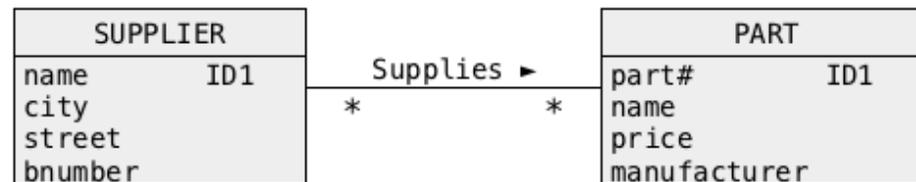

- A company **employs** an employee
- A company employes **many** employees
- An employee works for **none or one** company
- It is possible that a company has **no (zero)** employees

Association

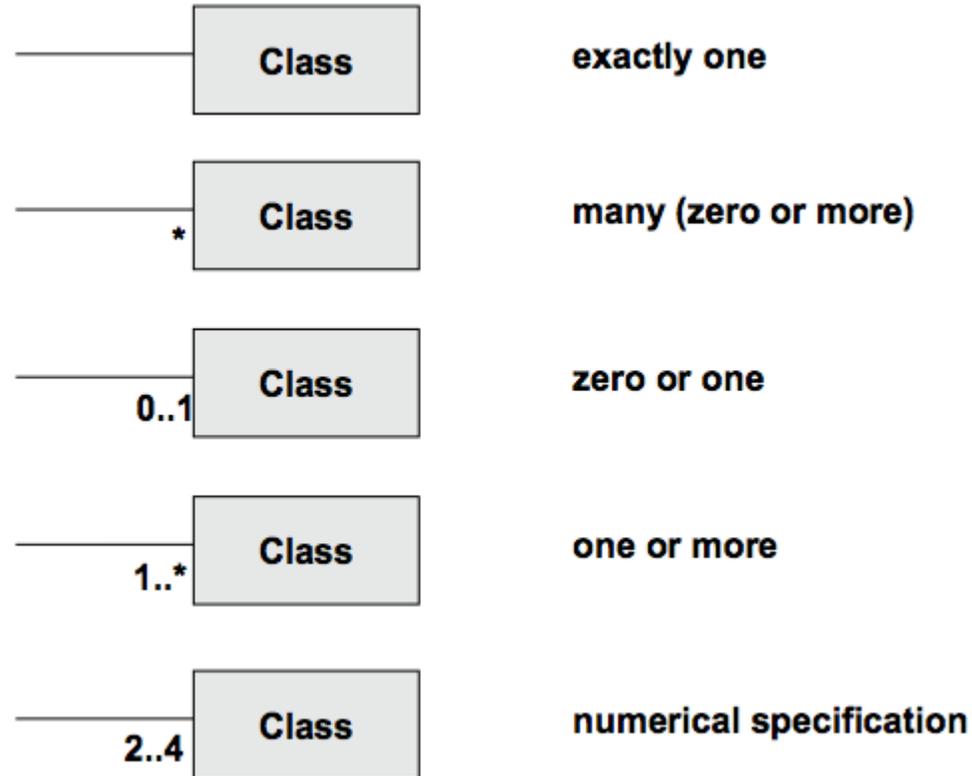

Many-to-many association

- A supplier **supplies** a part
- A supplier supplies **zero or more** parts
- A part is supplied by **zero or more** suppliers

Association

Summary

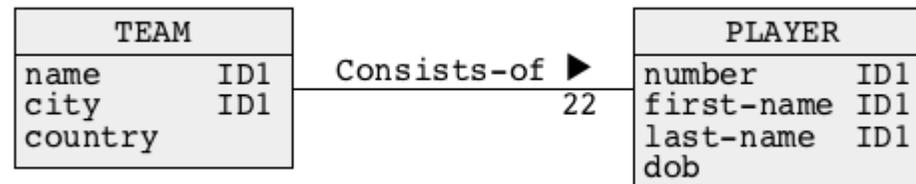

Association

More examples:

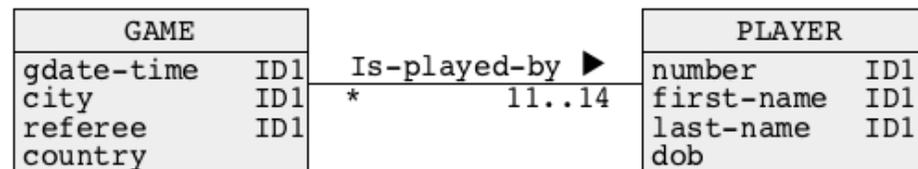

A team consists of **22** players

A player belongs to only **one** team

A game is played by **11** players plus maximum **3** substitutes

A player participates in **zero or more** games

Association

Link Attribute

Association Class

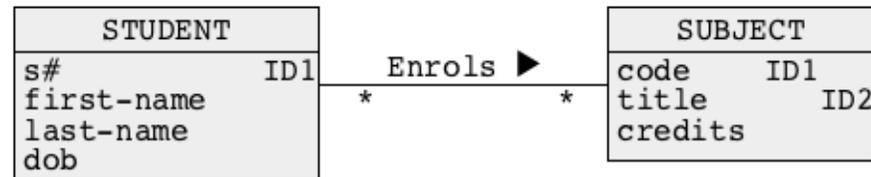

Qualification

Generalization

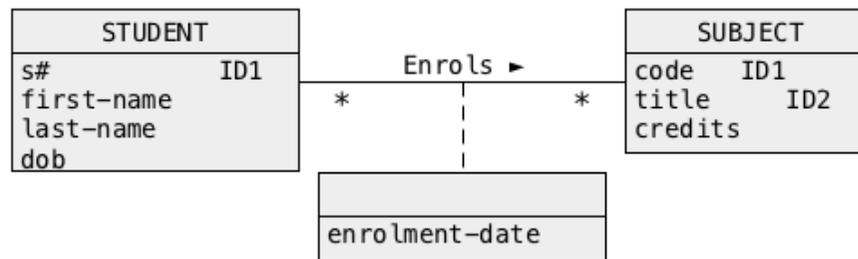

Link Attribute

A **link attribute** is an attribute that describes an **association**

A **student enrolls** a **subject**

An enrolment is performed on a given day, it means, that an enrolment is described by an **enrolment date**

A **link attribute** is graphically represented by a "class-like" rectangular box without a name of class in a header

Link Attribute

Why an attribute `enrolment-date` must be represented by a **link attribute** ?

For example, what about an attribute `enrolment-date` describing a class `STUDENT` ?

STUDENT	
<code>s#</code>	<code>ID1</code>
<code>first-name</code>	
<code>last-name</code>	
<code>dob</code>	
<code>enrolment-date[*]</code>	

Such design **is incorrect** because information about which subject has been enrolled by a student and on what date is missing

A student is associated with a set of `enrolment-dates`, however ...

... there is no link between the values of an attribute `enrolment-date` and the objects in a class `SUBJECT`

Link Attribute

So what about another option where an attribute `enrolment-date` describes a class `SUBJECT` ?

SUBJECT	
code	ID1
title	ID2
credits	
enrolment-date[*]	

Such design **is also incorrect** because information about who enrolled in a subject and on what date is missing again

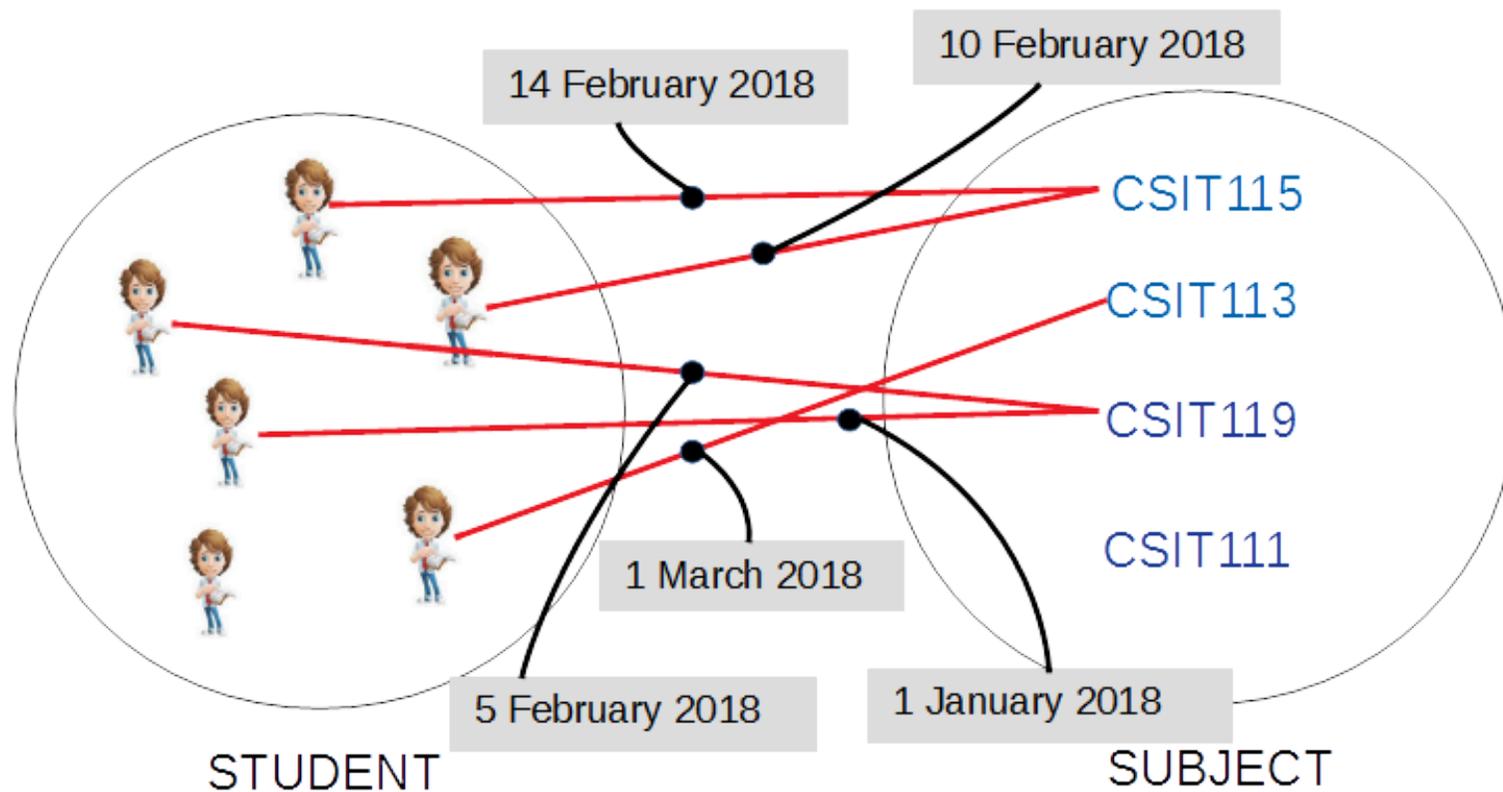

A subject is associated with a set of `enrolment-dates`, however ...

... there is no link between the values of an attribute `enrolment-date` and the objects in a class `STUDENT`

Therefore, the only option for an attribute `enrolment-date` is to be a **link attribute** that describes an association between a class `STUDENT` and a class `SUBJECT`

Link Attribute

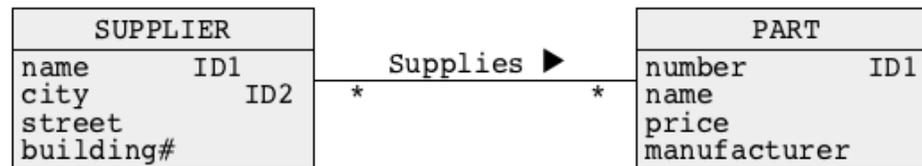

If an attribute `enrolment-date` describes an association `Enrols` between the classes `STUDENT` and `SUBJECT` then its values are like labels attached to the links between the objects from the classes `STUDENT` and `SUBJECT`

Link Attribute

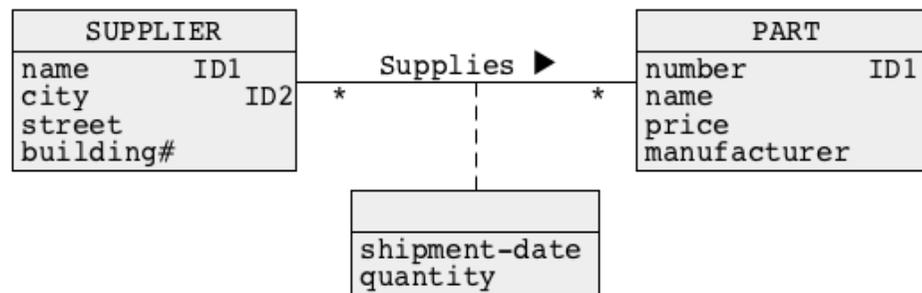

Another example of **link attribute**

A **supplier** **supplies** a **part**

A shipment of a part is performed on a given day, it means, that a shipment is described by an attribute **shipment date**

A shipment contains a given number of parts and it means, that a shipment is also described by an attribute **quantity**

Object Data Model

(Simplified) Class of Objects

Association

Link Attribute

Association Class

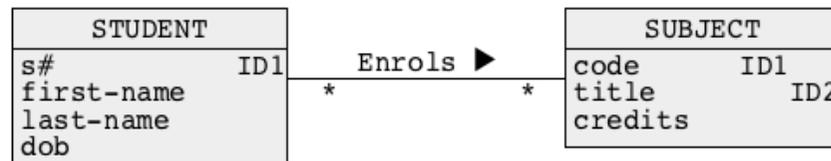

Qualification

Generalization

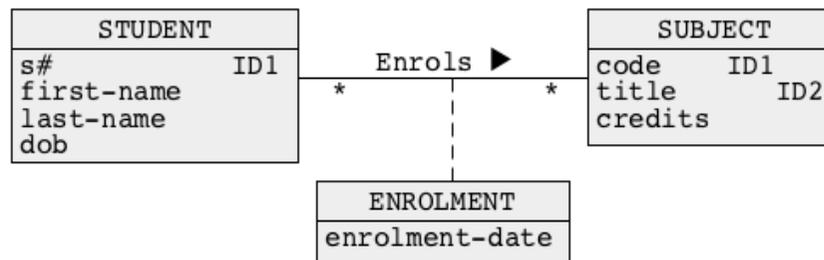

Association Class

An **association class** is a class that represents an **association**

A **student enrolls** in a **subject**

An enrolment is performed on a given day, it means, that an enrolment is described by an attribute **enrolment-date**

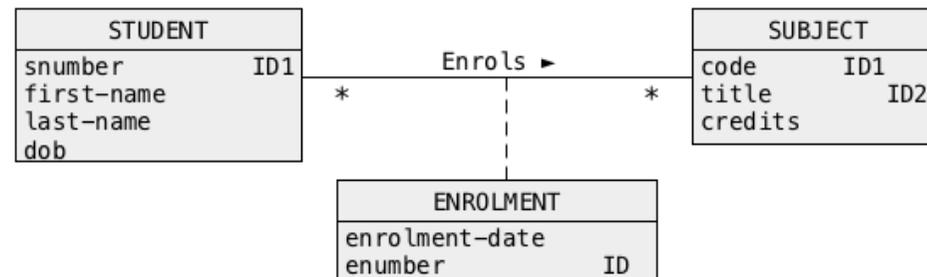

An **association class** **ENROLMENT** is graphically represented in the same way as a class of objects

Association Class

What about an **identifier** of an **association class** ?

An **association class** may have its own identifiers, for example **enrolment-number** in a class **ENROLMENT**

An **association class** that represents many-to-many association has a **default identifier** that consists of identifiers of the classes from both sides of association, for example a pair (**snumber**, **code**) in a class **ENROLMENT**

There is no need to include a **default identifier** into a description of a class of objects

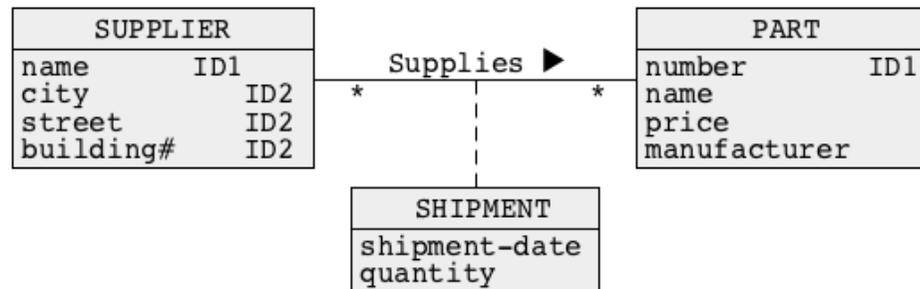

Association Class

Another example of **association class**

A **supplier** **supplies** a **part**

A shipment of a part is performed on a given day, it means, that a shipment is described by an attribute **shipment-date**

A shipment contains a given number of parts, it means, that a shipment is also described by an attribute **quantity**

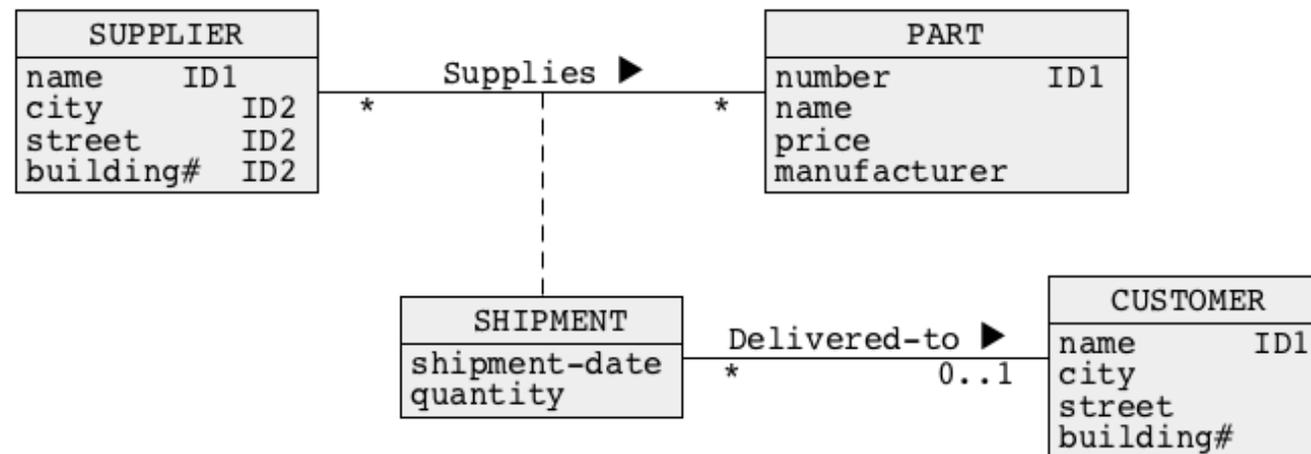

Association Class

What can we use **association classes** for ?

A **shipment is delivered to** a customer

An association **Delivered-to** connects the classes **SHIPMENT** and **CUSTOMER**

In a general case, it is possible to create associations between association classes and other classes of objects and between association classes and association classes

Association Class

Qualification

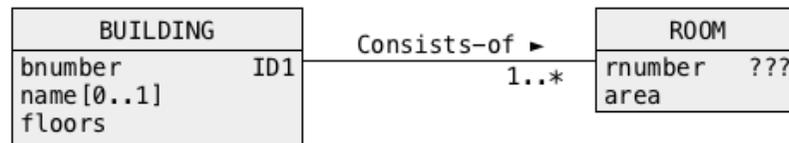

Generalization

Qualification

A **building** at a university campus is described by a unique **number**, optional **name** and the **total number of floors**

A **room** is described by a **number** and **area**

A **building** consists of **rooms**

What is an identifier of a class **ROOM** ?

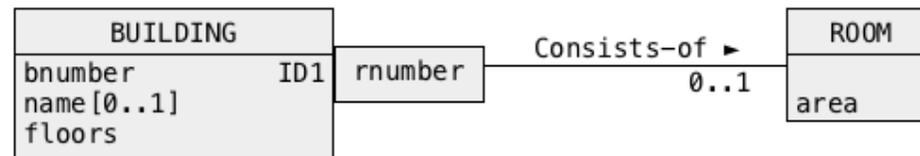

Identifier of a class **ROOM** is a **composite identifier** and it consists of the attributes **bnumber** from a class **BUILDING** and **rnumber** from a class **ROOM**

How do we represent composite identifiers that consist of attributes from more than one class ?

We use a **qualification** !

Qualification

A **building** at a university campus is described by a unique **number**, optional **name** and the **total number of floors**. A **room** is described by a **number** and **area**. A **building** consists of **rooms**

A **qualification** is represented by a rectangle with one or more attribute names

In the example above a **qualification** means that in a given **building** there is at most one **room** with a given **number**

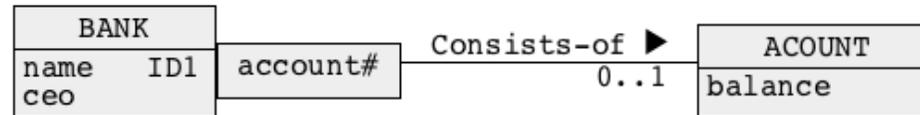

It also means that an attribute **rnumber** is a **local identifier** in a class **ROOM**, i.e. all **rooms** in a given **building** have different **numbers**

A pair of attributes (**bnumber**, **rnumber**) is a **default identifier** of a class **ROOM**

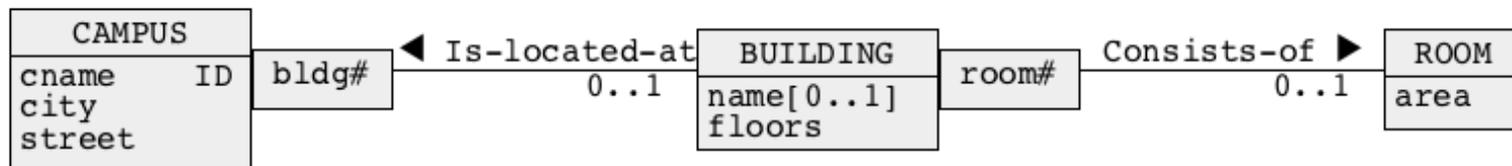

Qualification

More examples:

A bank account is located at a bank

A campus consists of buildings and buildings consist of rooms

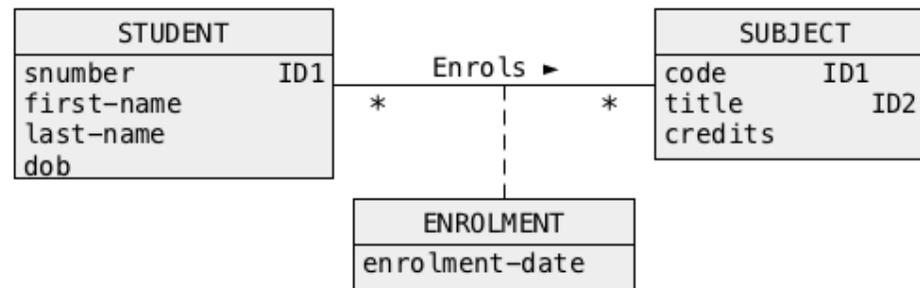

Qualification

Sometimes qualification is needed for **many-to-many** associations

For example, if we consider a pessimistic view of **students** who **enrol** in **subjects** then sometimes a student must enrol in the same subject more than one time (well, ... you know when it happens and why it is a "pessimistic" view of reality)

Some time ago we created the following design

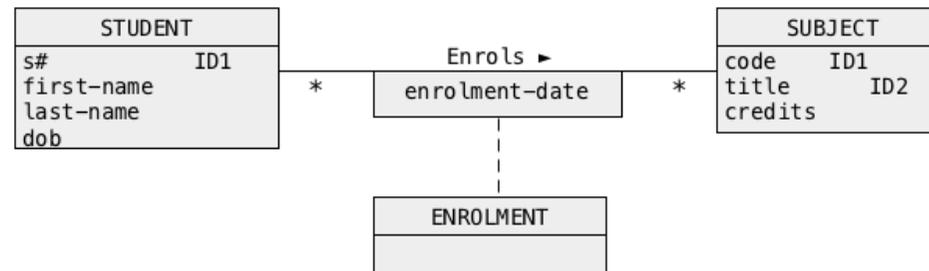

But, ... if enrolment is repeated several times then a pair of attributes (**snumber**, **code**) is no longer an identifier of a class **ENROLMENT** !

Qualification

If enrolment is repeated several times then an identifier of a class **ENROLMENT** is a triple (snumber, code, enrolment-date)

How is this represented graphically ?

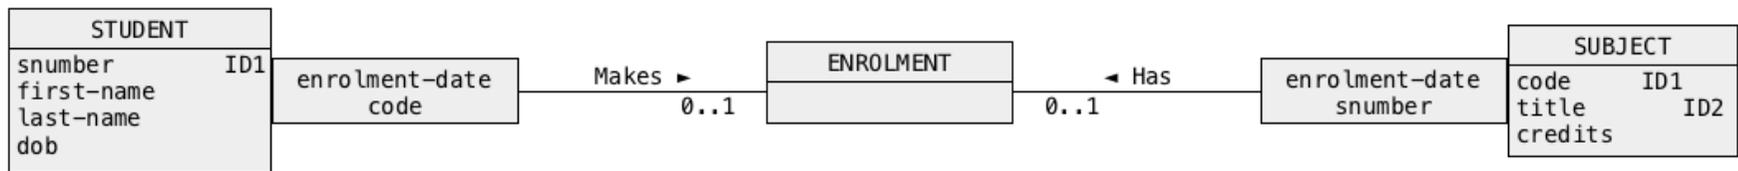

It is represented by a **qualification** of the middle part of the association **Enrols**

Qualification of the middle part of many-to-many association means, that an identifier of **association class** consists of an identifier of a class on the left hand side of association, identifier of a class on the right hand side of association, and qualification attribute(s)

Qualification

A qualification of the middle part of many-to-many-association is equivalent to the following two single-side qualifications of one-to-many association and many-to-one association

Association

Link Attribute

Association Class

Qualification

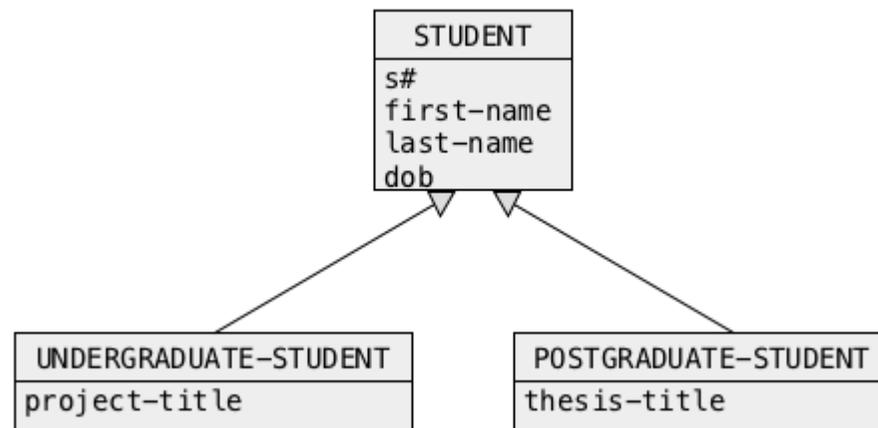

Generalization

Generalization

A **generalization hierarchy** represents **Is-a-subset** relation between the classes of objects

A set of all undergraduate students is a subset of a set of students, it means, that an undergraduate student **IS-A** student

A set of all postgraduate students is a subset of a set of students, it means, that a postgraduate student **IS-A** student

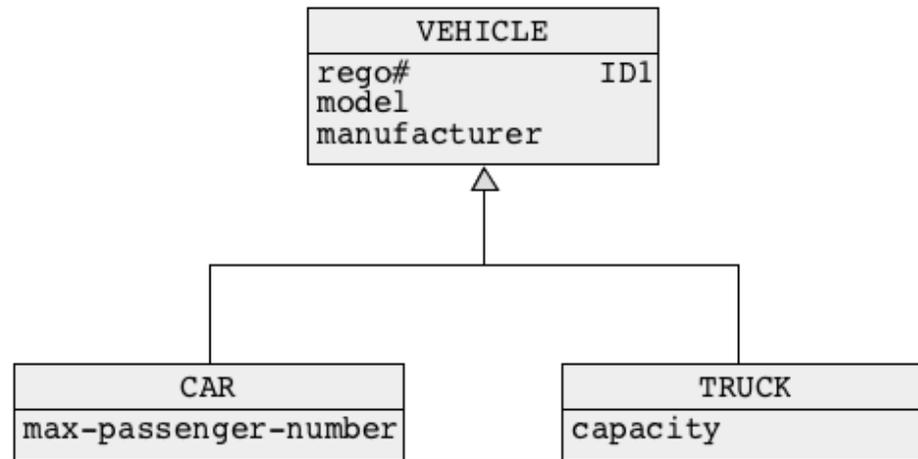

A **generalization hierarchy** is built with arrows pointing from a **subclass** to a **superclass**

Generalization

Another graphical notation for **generalization hierarchy**:

A car **IS-A** vehicle and a truck **IS-A** vehicle

To create a nice effect the arrows can be "joined" into a single arrow

Entity-Relationship Modeling

Entity-Relationship Modeling is another graphical conceptual modeling notation

It is presented in your textbook

Graphically it is very similar to Object Data Model

The following concepts from the notations are equivalent:

- Class of objects = Entity type
- Object = Entity instance
- Association = Relationship
- Identifier = Primary key or Candidate key
- Qualification = Weak entity type
